

## Veneer Teeth Coquitlam

Tooth-like ceramic veneers are custom-fabricated thin shells that are to be adapted to the front surface of your teeth. They can be made to mask chips, cracks, acute staining in teeth, to rectify spacing or the alignment of the teeth, and to protect worn down tooth enamel.

Veneers are repeatedly made with translucent porcelain materials that are really natural looking giving clients a brighter whiter impeccably aligned teeth. Often, these restorations will get grouped with dental cosmetics due to these assumed benefits.

### Aesthetic Veneers

Some of the methods that veneers may help upgrade your smile are:

**Damaged tooth enamel:** After a period of time, the thin hard shell that protects your teeth may become worn, dulled, and discoloured. Now and again this staining and deterioration can be due to natural use, be a consequence of damage or may even come from a genetic predisposition; yet, many times your day by day eating plus drinking habits (coffees, teas, dark colas, tobaccos, prescription medicines) cause most of the discolouration.

**Natural wearing of the teeth:** When individuals get older teeth will organically start to break down and timeworn teeth are more prone to cracking, ridging and chipping.

**Natural physiology:** Certain people may be predisposed to developing uneven teeth or irregular spacing of the teeth that can spread wider as they get older.

**Asymmetrical teeth:** Jagged teeth can manifest itself from too much tooth grinding or general damage.

### Ceramic Veneers and composite Resin Veneers

Nearly all veneers are made from two diverse materials: one is a synthetic resins made from plastics, silica, and other synthetic resins. The other is a porcelain material made from ceramics. Usually these materials can be created for use in a specialized dental laboratory, while your oral health professional may craft veneers out of synthetic resins in-office and position them onto a tooth in the course of a visit. Veneers that are indirectly built, fabricated in a dental laboratory, are cemented to the teeth with bonding agents usually made from synthetic resins. Of the two methods, porcelain veneers are more durable but are also more expensive.

### When is it appropriate to use dental veneers?

Bonding is an economical and efficient dental restoration for slight chips and cracks in the teeth. These kinds of minor issues can be dealt with by using a composite "white filling." A synthetic material is cemented to the tooth in order to fill the chips or splits in addition to better protection of the encompassing tooth structure. Other than the more important cases of drabness, wear, yellowing, chipping, splintering, spacing, or irregular teeth, veneers may possibly be suggested as the more suitable solution.

### Veneers or Bleaching?

Occasionally bleaching is the optimal alternative for moderately discoloured teeth, but treatments need to be sustained over time. In numerous incidences, veneers can proffer a simpler option. The positioning of veneers calls for the teeth to be readied or shaped before being fitted with a custom-fabricated shell. This process will permanently change the teeth and is for that reason not recommended if your natural teeth are functionally and esthetically healthy.

If chosen, custom veneers can solve incidences of acute staining. They also have the added benefits of longevity and strength with the capacity to enhance the overall appearance of the mouth and smile. Though veneers can necessitate more of a commitment than bleaching programs, the results are generally worth it.

Veneers may only call for tiny amounts of tooth reshaping prior to being placed due to them being so slender. However, once they are in position, they offer a robust and sturdy restoration. This does not mean that appropriate carefulness should not be taken. The veneers are slim porcelain shells that can become damaged if they are abused.
