

Cosmetic Gum Surgery Coquitlam

Evaluations of the gum tissues can be performed with digital photographs at some point in an appointment to the oral health care provider. By looking at the height of the gumline in relation to the other teeth, the oral health care professional can determine how symmetrical the gum tissues are, so they can try to fashion your smile with natural looking gum lines.

There are two different therapies dental clinicians use to flatten out the gum tissues. The first is a gum lift and the second is the periodontal graft. The gum lift calls for the taking away gum tissues to even out both sides of the mouth. The periodontal graft on the other hand requires the adding of periodontal tissues to a region which has serious gum recession or a poor root structure. This will help cover the tooth at the same time as also flattening out the gums around the adjacent teeth.

A periodontal specialist referred to as a Periodontist may be needed to perform the therapies based on how widespread the work required is. Healing time has a tendency to take about three to twelve weeks. Note - these procedures might be needed prior to the installation of any veneers or crowns.
